

Platyceratid gastropods – stem group of patellogastropods, neritimorphs or something else?

JIŘÍ FRÝDA, PATRICK R. RACHEBOEUF, BARBORA FRÝDOVÁ, LENKA FERROVÁ, MICHAL MERGL & STANISLAVA BERKYOVÁ

A systematic study of Silurian and Devonian platyceratid gastropods provides new data on their early shell ontogeny. Typical cyrtoneritimorph protoconchs were found in *Praenatica cheloti* (Oehlert & Oehlert, 1887) from the Lower Devonian strata of Brittany (W France). The same protoconch type, as in *Praenatica* Barrande in Perner, 1903, was earlier documented in *Orthonychia* Hall, 1843. Both of the latter taxa have often been considered to be subgenera of *Platyceras* Conrad, 1840. However, Silurian and Devonian species of *Platyceras* from the Barrandian area develop quite different protoconchs (orthostrophic and tightly coiled), similar to those found earlier in different species of the family Naticopsidae Waagen, 1880. Current data suggests that Paleozoic platyceratids represent a diphyletic group. The nature of their protoconchs (development of a true larval shell) testifies against the hypothesis that the Paleozoic platyceratids are the stem group for the Patellogastropoda. However, the derivation of modern neritimorphs from Paleozoic “platyceratids” with tightly coiled protoconchs or from the naticopsids seems to be probable. The strongly convolute neritimorph protoconch (apomorphy of neritimorph crown-group) probably originated after the Permian/Triassic mass extinction event, but before the Late Triassic. • Key words: Gastropoda, phylogeny, Platyceratoidea, Neritimorpha, Patellogastropoda, Cyrtoneritimorpha, protoconch morphology.

The phylogenetic position of fossil animals is often uncertain due to a limited number of characters bearing a phylogenetic signal. This situation is more frequent in extinct animal groups because their anatomical features cannot be inferred from related living taxa, the latter often characterized not only by their morphological, but also by anatomical and genetic data. Difficulties with recognition of the correct phylogenetic position of fossil animals also increase with their geological age. This rule may be well illustrated by fossil members of the class Gastropoda. Gastropods form about 20 percent of all living marine species in Recent marine ecosystems, but the vast majority of their families originated after the crisis at the Cretaceous/Palaeogene boundary (Stanley 2007 and references therein). In addition, Bouchet *et al.* (2005) showed that the majority of gastropod families are extinct. The phylogenetic position of

these extinct gastropods in relation to higher taxa may be inferred only from the morphological features of their fossilized shells. Generally morphological characters of the teleoconchs (*i.e.*, post-metamorphic shells) seems to represent a good character source for species- to family-level taxonomy. However, teleoconchs bear few or no phylogenetic signals useful for analysis of their order-level position. In contrast to the teleoconchs, the pattern of early shell ontogeny as well as the shell microstructure provides data which seems to be more useful for analysis of the higher phylogenetic relationships of fossil gastropods. Studies of living gastropods (*e.g.*, Bandel 1982) showed that the pattern of early shell ontogeny is a good apomorphic character of high-level taxa. Each of four main groups of living orthogastropods (all gastropods excluding the patellogastropods) may be characterized by a unique pattern of early

shell ontogeny (Bandel 1982, 1997; Ponder & Lindberg 1997, and references therein). In addition, the shell ontogenetic pattern is very stable for long temporal ranges which make the recognition of major phylogenetic lineages of living gastropods in the past possible. Analysis of these characters in fossil gastropods has shown that all four living orthogastropod clades (Caenogastropoda, Heterobranchia, Neritimorpha, and Archaeogastropoda) may be traced back to the Paleozoic (Bandel 1997; Frýda 1998a–c, 1999; Nützel 1998; Nützel *et al.* 2000; Bandel 2002a, b; Frýda & Rohr 2004, 2006; Frýda *et al.* 2008a, and references therein). Moreover, studies of the shell ontogeny in fossil gastropods have revealed the presence of several Paleozoic gastropod clades which existed for a long time and which were characterized by unique ontogenetic patterns unknown in post-Paleozoic gastropods (Frýda 1999a, Frýda & Rohr 2004, Frýda *et al.* 2008a and references therein). However, our knowledge of the shell ontogeny of Paleozoic gastropods is still poor. The present short paper deals with the discovery of protoconchs in Early Devonian platyceratid gastropods from Brittany (France) and is focused mainly on its significance for an understanding of their higher phylogenetic position.

Platyceratids from Brittany

On-going revision of the large fossil collections of Devonian gastropods from Brittany (W France) revealed an unusually high number of well-preserved shells belonging to different platyceratid taxa. The almost uncoiled shells of *Orthonychia protei* (Oehlert, 1883) enabled an analysis of the infraspecific variability of shape, size and position of the muscle scar (Frýda *et al.* 2008b). On the other hand, coiled shells of some platyceratids revealed a well preserved juvenile whorl making the study of their early shell ontogeny possible. Since the discovery of unusual protoconchs in the Early Devonian *Vltaviella reticulata* Frýda & Manda, 1997, our efforts to find other platyceratoideans with a well preserved protoconch has been focused on many Silurian and Devonian gastropod faunas from Europe, Asia, Australia and North America. Characteristic cyrtoneritimid morph protoconchs were found in some of these faunas, but typically they were isolated or attached to very juvenile shells, which did not provide sufficient shell characters for determination of their specific as well as generic assignments. Platyceratid species are based, like the vast majority of the Paleozoic gastropod species, on adult shells which frequently do not preserve juvenile whorls. Previous research has provided evidence that isolated cyrtoneritimid morph protoconchs are very common in Early Paleozoic strata (see discussion in Frýda 1999; Nützel & Frýda 2003; Nützel *et al.* 2006, 2007a), however, because of this it is difficult or even impossible to determine to which species

or genus the discovered protoconchs belong. The Early Devonian material of Brittany provides a unique opportunity to study well-preserved protoconchs in adult platyceratid shells. Such conditions are very rare even in living marine gastropods.

The platyceratid gastropods described here come from localities NW of Laval in the eastern part of the Massif Armoricain, in the Mayenne department, W France. The locality of La Baconnière is situated about 15 km NW of Laval and is famous for its very abundant, well-preserved fossils, among which are numerous gastropods. The best known localities are the La Poupardière and La Jallerie quarries, which are between 1.5 km and 2.5 km S of La Baconnière. The Saint Roch quarry, N of Saint Ouen-des-Toits, is close to the La Jallerie quarry, and situated about 3 km S of La Baconnière. Maps and a detailed description of the above-mentioned localities can be found in the monographs of Morzadec (1971) and Racheboeuf (1976).

Generic position of platyceratids from Brittany

Since the middle of the nineteenth century several tens of Early Devonian gastropod species were described from Brittany (e.g., Verneuil 1850; Oehlert 1877, 1881, 1883; Oehlert & Oehlert 1887; Oehlert & Davoust 1879; Renaud 1930, 1942). Gastropods placed into the superfamily Platyceratoidea Hall, 1879 form only a small part of the species known from Brittany. Seven gastropod species, described under the names *Platyceras lorieri* de Verneuil, 1850, *Platyceras dentalium* Hall, 1861, *Platystoma? janthinoides* Oehlert, 1877, *Platystoma? naticopsis* Oehlert, 1877, *Diaphorostoma (Strophostylus) cheloti* Oehlert & Oehlert, 1887, *Platystoma naticopsis v. undulata* Oehlert, 1881, and *Acroculia protei* Oehlert, 1883 are typical platyceratids. Four additional species – *Naticopsis sirodotti* Munier-Chalmas, 1876, *Naticopsis filosa* Oehlert & Oehlert, 1887, *Naticopsis elegantula* Oehlert & Davoust, 1879, and *Naticopsis bigsbyi* Oehlert & Davoust, 1879 – described as belonging to the genus *Naticopsis* M'Coy, 1844, may also be members of the platyceratoidean group. The generic position of *Platyceras lorieri*, *Platyceras dentalium* and *Acroculia protei* is obvious (see Oehlert 1881, pl. II, and Frýda *et al.* 2008a) and they may be placed in the genus *Orthonychia* Hall, 1843. In addition, the first two species may be even conspecific (see de Verneuil, 1850, pl. II, figs 1, 2). The core group of the platyceratids from Brittany is formed by *Diaphorostoma (Strophostylus) cheloti*, *Platystoma? janthinoides*, *Platystoma? naticopsis* and *Platystoma naticopsis v. undulata*. In 1877, Oehlert described two species from the locality La Baconnière which he questionably placed in the genus *Platystoma* (later correctly cited by

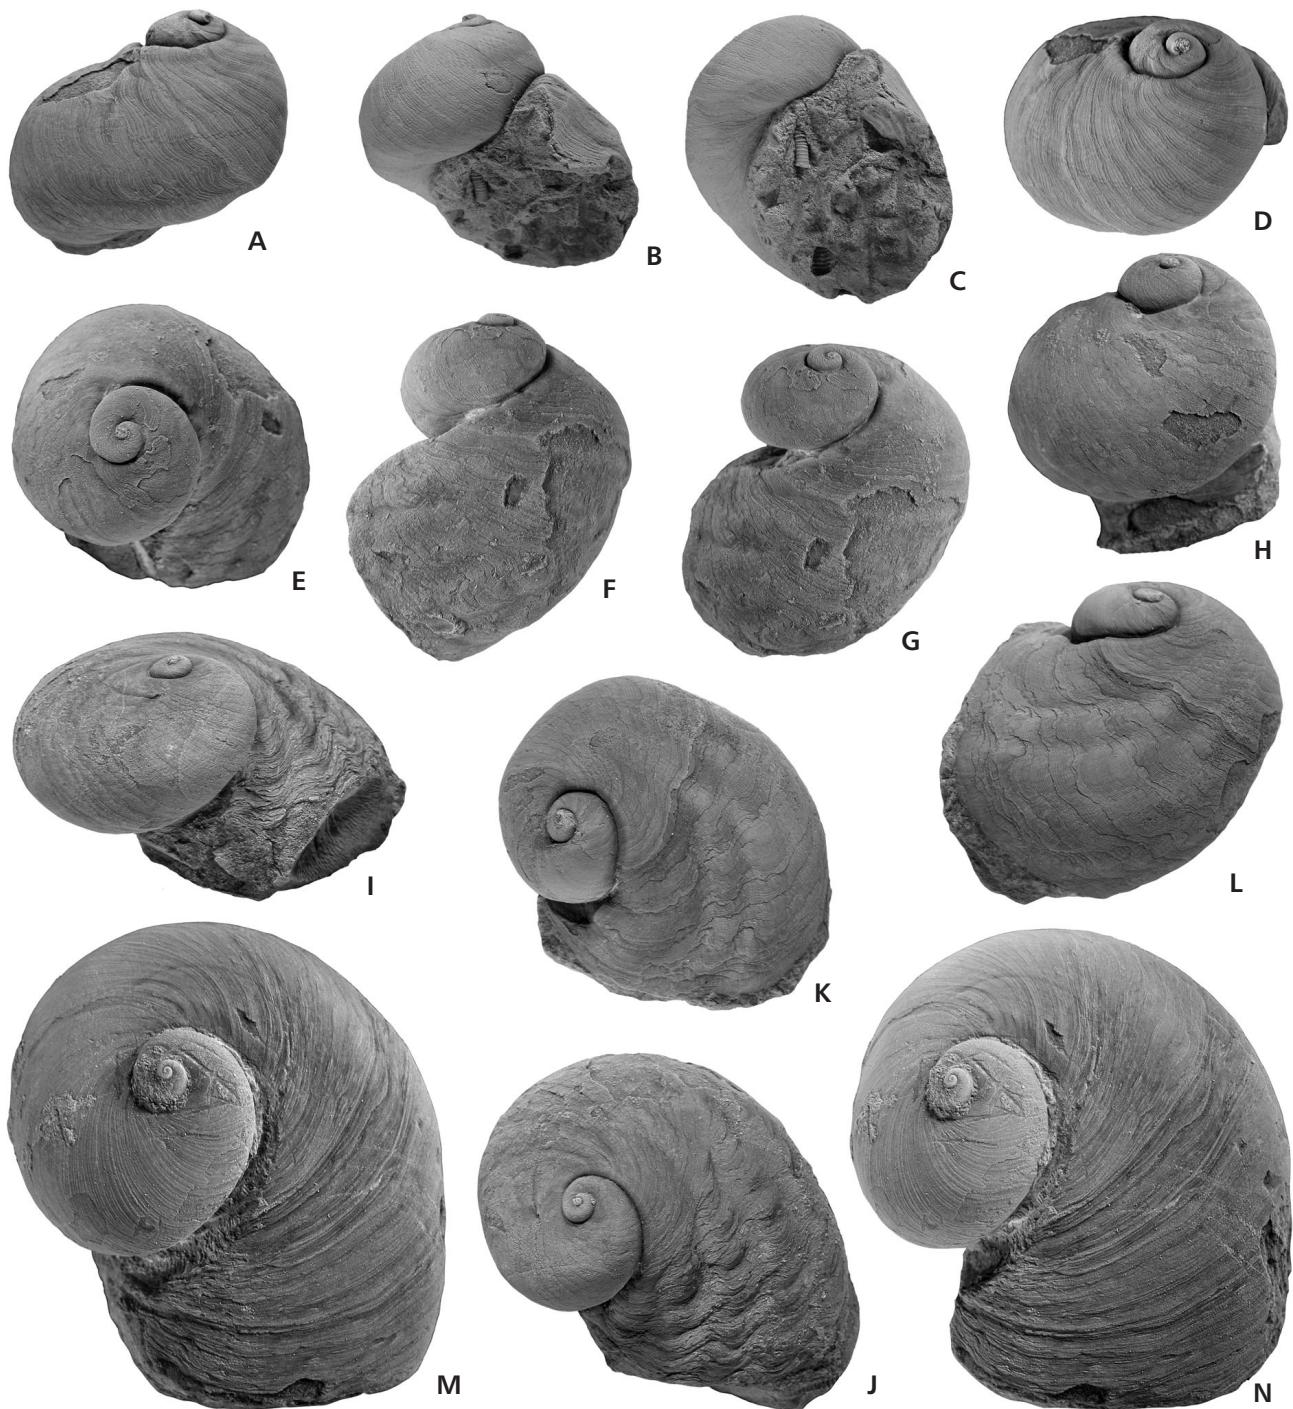

Figure 1. *Platystoma? naticopsis* [= *Praenatica naticopsis*] Oehlert, 1877 and *Diaphorostoma (Strophostylus) cheloti* [= *Praenatica cheloti*] Oehlert & Oehlert, 1887 from the Lower Devonian strata of Brittany (France). • A–D – holotype of *Platystoma? naticopsis* Oehlert, 1877 [= *Praenatica naticopsis*] figured on pl. 9, fig. 10, UBO [= Université de Bretagne Occidentale] collection, No. 2560 (Musée d'Histoire Naturelle, Laval, No. ML-PAL-00401), La Poupartière quarry near La Baconnière. • E–H – *Praenatica naticopsis* from La Baconnière (about 15 km NW of Laval), topotype No. ML-PAL-00402 from the same collection as the holotype. • I–J – *Praenatica naticopsis* from La Baconnière, topotype No. ML-PAL-00403 from the same collection as the holotype. • K, L – *Platystoma? naticopsis* Oehlert, 1877 [= *Praenatica naticopsis*] figured by Renaud (1942) on pl. IX, fig. 7, UBO collection, No. 2561 (No. ML-PAL-00404), La Poupartière quarry near La Baconnière. • M, N – *Diaphorostoma (Strophostylus) cheloti* Oehlert & Oehlert, 1887 [= *Praenatica cheloti*] from the Saint Roch quarry (about 3 km S of La Baconnière) with preserved cyrteneritimorph protoconch, No. ML-PAL-00405. All shells $\times 1.5$.

Oehlert as *Platystoma* Conrad, 1842). Both species seem to be very similar (judging from figures and description in Oehlert 1877). On-going revision of these two species from Brittany has resulted in some problems. Only the holotype of *Platystoma?* *naticopsis* Oehlert, 1877, (figured on pl. 9, fig. 10 and deposited in the UBO [= Université de Bretagne Occidentale] collection under the number 2560 – see Fig. 1A–D) was found. However, the holotype of the second species, *Platystoma?* *janthinoides* Oehlert, 1877, which should be in the same collection was not found or was not recognized by the senior author among the many tens of platyceratid specimens (partly not numbered) in the UBO collection and is probably lost. Comparison of those platyceratid specimens with the holotype of *Platystoma?* *naticopsis* Oehlert, 1877, revealed that the latter species is rather variable as had already been mentioned by Oehlert (1877). The platyceratids from the locality La Baconnière seem to form a morphological group belonging to one species which also includes the holotypes of *Platystoma?* *naticopsis*, *Platystoma?* *janthinoides*, and *Platystoma naticopsis* v. *undulata*. However, we are leaving this question open until the time when a revision of all platyceratids from Brittany is finished and when the loss of the holotype of *Platystoma?* *janthinoides* is confirmed. Later Oehlert, in 1887, described *Diaphorostoma (Strophostylus) cheloti* also from the locality La Baconnière and mentioned that it differs from his *Platystoma naticopsis* by its apertural shape, growth lines, and shell size. However, these shell characters seem to vary during ontogeny in the studied specimens and, therefore, they cannot be used for safe (if any) species-level taxonomy. Thus, *Diaphorostoma (Strophostylus) cheloti* may also be conspecific with *Platystoma naticopsis* (compare specimens figured here in Figs 1 and 2). Regardless of the latter problem, all the above-mentioned species belong to the same genus. As mentioned by Knight (1941) *Diaphorostoma* Fischer, 1885 is an objective synonym for *Platystoma* Conrad, 1842. Barrande, in a private letter (May 12, 1882) to Daniel Oehlert, expressed his opinion that some of Oehlert's *Platystoma naticopsis* may belong to his new genus *Praenatica* (Horný & Henry 1999). However, the name *Praenatica* was first published by Bigsby (1868) as a *nomen nudum* and its valid publication by Perner in 1903 is dated much later (see detailed description of that problem by Knight 1941 and Horný & Henry 1999). We agree with the conclusions made by Barrande (letter of May 12, 1882) and Horný & Henry (1999) and place all the above-mentioned French species, *Diaphorostoma (Strophostylus) cheloti*, *Platystoma?* *janthinoides*, *Platystoma?* *naticopsis* and *Platystoma naticopsis* v. *undulata*, in the genus *Praenatica*. In addition, *Praenatica gregaria* (Barrande in Perner 1903), a species very common in the Koněprusy Limestone [Praha Formation; Pragian–early Emsian (see Carls *et al.* 2008), Early Devonian], may also belong to this species as already

mentioned by Barrande (letter of May 12, 1882) and Horný & Henry (1999). We follow here this generic placement for the taxa from Brittany, but leave their species-level revision for future study.

Early ontogeny of *Praenatica*

Several adult shells, some of them determined by Oehlert as *Diaphorostoma (Strophostylus) cheloti* [= *Praenatica cheloti* (Oehlert & Oehlert, 1887)], were found with relatively well preserved protoconchs. The maximum size of the teleoconchs in *Praenatica cheloti* with preserved protoconchs is 5 cm (Fig. 2) and the preservation of their protoconchs was probably positively influenced by the muddy facies in which specimens of *Praenatica cheloti* were found. The protoconchs of *Praenatica cheloti* are open-coiled, fish-hooklike, and their diameter is about 0.5 mm. The general shape as well as size is constant in these protoconchs (Fig. 3).

A systematic effort to find preserved protoconchs in the Pragian *Praenatica gregaria* (Barrande in Perner 1903) from the Koněprusy Limestone (Praha Formation, Barrandian area) was not fruitful despite the fact that the senior author examined many hundreds of shells of *Praenatica gregaria* mainly from the Plešivec Quarry (SE of Koněprusy and SW of Měňany) for that character. The only exception is a specimen found during the revision of Paleozoic gastropods from the Schary collection (a large collection of Paleozoic fossils from the Barrandian area, Czech Republic, deposited since the nineteenth century in the Museum of Comparative Zoology, Harvard University). The latter specimen was labeled as coming from Koněprusy and without doubt it belongs to *Praenatica gregaria*. In addition, the character of the limestone surrounding the shell indicates its origin from the Koněprusy Limestone. However, the protoconch of the above-mentioned specimen is not completely preserved (its apex is missing), but its remains show a distinct cavity in the center of the first whorl (Fig. 3H, I). Thus, the remains of the protoconch in the Bohemian *Praenatica gregaria* seem to be identical with the protoconchs of *Praenatica cheloti* in its size and shape (compare Fig. 3A–F with 3H–I).

Early ontogeny of platyceratid gastropods

Preservation of early ontogenetic shells of Paleozoic and early Mesozoic gastropods is rare because protoconchs are small, delicate, and aragonitic. Consequently, they are commonly removed from the fossil record by taphonomic and diagenetic processes. For this reason the fossil record of platyceratid protoconchs is relatively poor, similar to that of all other Paleozoic gastropods. A systematic effort to

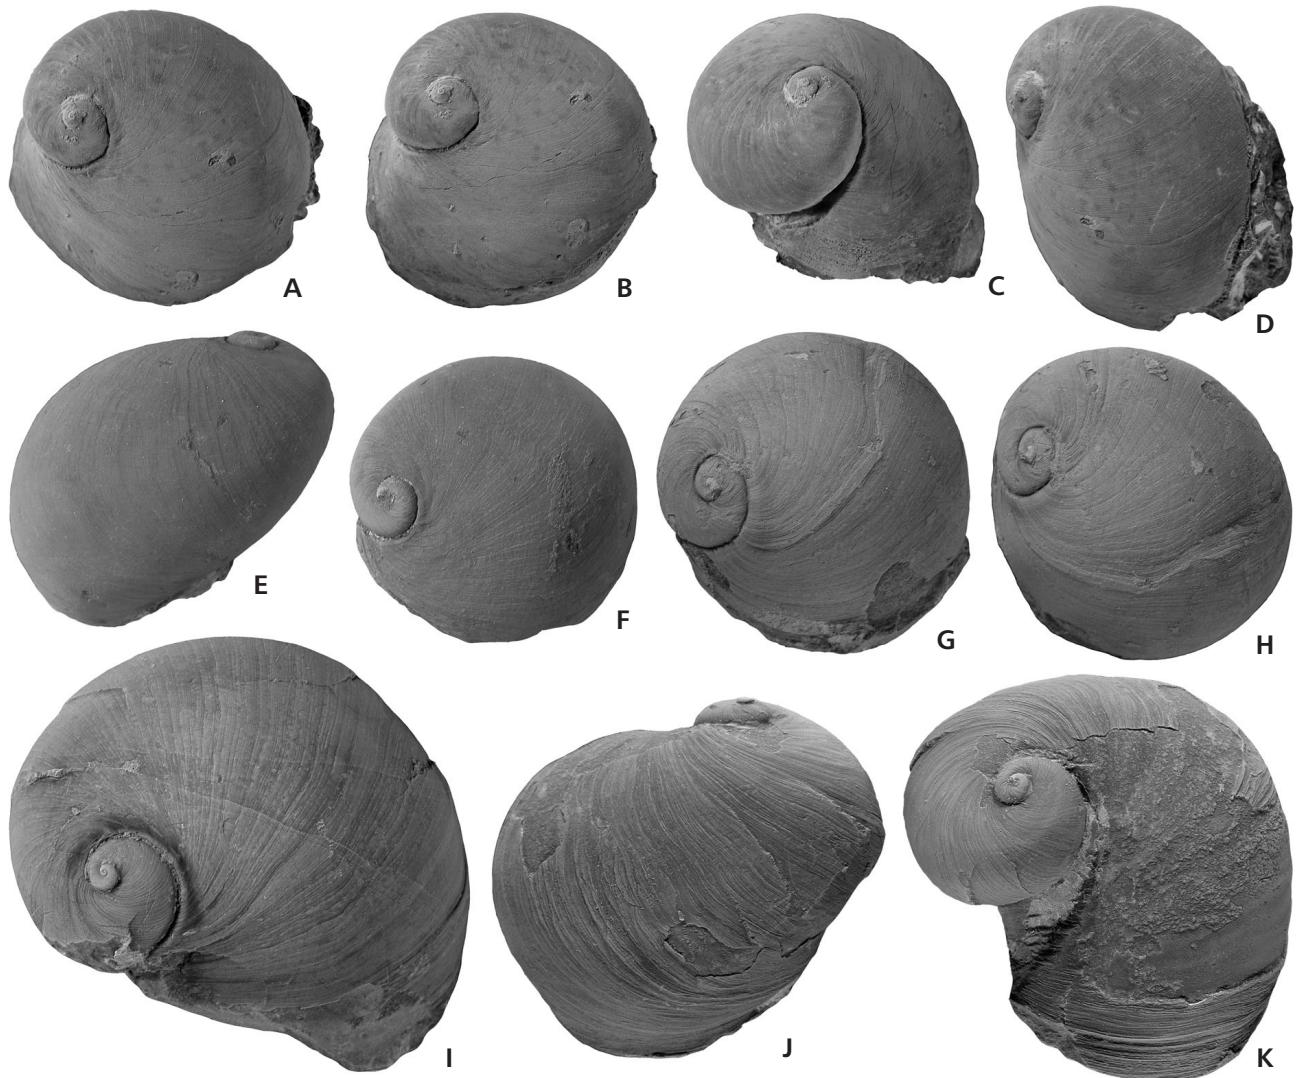

Figure 2. *Diaphorostoma (Strophostylus) cheloti* [= *Praenatica cheloti*] Oehlert & Oehlert, 1887 from the Lower Devonian strata of Brittany (France). • A–D – *Praenatica cheloti* from the Saint Roch quarry (N of Saint Ouen-des-Toits and about 3 km S of La Baconnière), the same specimen or a specimen similar to that figured by Oehlert & Oehlert (1887) on pl. VI, fig. 8c (Musée d'Histoire Naturelle, Laval, No. ML-PAL-00406); the shell is in a dark grey limestone with white brachiopods and has a well preserved cyrtoneritimorph protoconch (see Fig. 3A–C). • E, F – *Praenatica cheloti* from the same limestone type as Fig. 2A–D and labeled as coming from La Baconnière, collection ML 06883 (No. ML-PAL-00407). • G, H – paratype of *Diaphorostoma (Strophostylus) cheloti* [= *Praenatica cheloti*] figured on pl. VI, fig. 8b by Oehlert & Oehlert (1887), UBO collection, No. 2562 (No. ML-PAL-00408), the Saint Roch quarry (N of Saint Ouen-des-Toits and about 3 km S of La Baconnière). • I–K – two shells of *Praenatica cheloti* from the Saint Roch quarry, topotypes No. ML-PAL-00409 (I) and No. ML-PAL-00410 (J, K) from the same limestone type as Fig. 2A–D. All shells × 1.

find preserved protoconchs in members of the family Platyceratidae resulted in several unexpected discoveries. Frýda (1998a, b, 1999) provided evidence that teleoconchs of some presumed platyceratid gastropods bear unusual protoconchs with openly coiled, fish-hooklike morphology and these protoconch types may be traced from the Early Ordovician to the Late Permian, thus, lasting for about 250 million years. He interpreted this group as an independent gastropod lineage, which may represent an ancestral group for Neritimorpha, and therefore named it Cyrtoneritimorpha (Frýda 1998a–c, 1999). Cyrtoneritimorph protoconchs

are relatively common in the Ordovician, Silurian and Lower Devonian strata, but during the Carboniferous and Permian they became rare and no record exists for them in post-Paleozoic times (Frýda & Manda 1997, Frýda 1999, Frýda & Bandel 1999, Heidelberger & Bandel 1999, Frýda & Heidelberger 2003). Even though cyrtoneritimorph protoconchs are common in the Early Paleozoic, there are only a few examples with the protoconch found in an adult teleoconch, making species-level determination possible. Up to now, cyrtoneritimorph protoconchs were found in the following species – Silurian *Kramerella hornyi* Frýda &

Heidelberger, 2003; Devonian *Vltaviella reticulata* Frýda & Manda, 1997; *Soetenichia girzenbergense* (Kirchner, 1915); *Eifelcyrtus blodgettii* Frýda & Heidelberger, 2003; *Praenatica cheloti* (Oehlert & Oehlert, 1887); Carboniferous *Orthonychia parva* (Shumard & Swallow, 1858); and Permian *Orthonychia bowsheri* Yochelson, 1956 (Fig. 5). However, there is very rich fossil material of isolated cyrtoneritimorph protoconchs from different stratigraphical levels of Ordovician to Lower Devonian strata showing that the cyrtoneritimorphs were common in the Early Paleozoic gastropod faunas. Open-coiled protoconchs were found in several clades of Paleozoic gastropods such as the Euomphalomorpha, Peruneloidea, Macluritoidea, and Cyrtoneritimorpha (Frýda 1999; Bandel & Frýda 1998, 1999; Nützel 2002; Frýda & Rohr 2004, 2006; Frýda *et al.* 2008a). A documented general trend towards decreasing proportions of open-coiled protoconchs through the Paleozoic may also explain the decrease in frequency of cyrtoneritimorph protoconchs (Nützel & Frýda 2003; Frýda *et al.* 2008a).

On the other hand, in addition to the cyrtoneritimorph protoconchs, Frýda (1998a,b, 1999) reported the occurrence of tightly coiled, but not convolute, orthostrophic protoconchs in some Paleozoic “platyceratoidean” gastropods. Such protoconch morphology was later documented in some members of the Platyceratidae, Plagiothyridae, Naticopsidae, Nerrhenidae, and Oriostomatoidea (Yoo 1994, Bandel & Frýda 1999, Bandel & Heidelberger 2001, Nützel & Mapes 2001, Nützel *et al.* 2007a). Some new findings also revealed this protoconch type in “*Platyceras*” sp. from the Chýnice Limestone (middle Emsian; Devonian) of the Barrandian area (Fig. 4A–C). Similar early shell morphology was found in the Upper Silurian “*Platyceras*” sp. from the same area (see Fig. 4E, F, H, I). Even though the first shell whorl is not preserved in any of the Silurian specimens, the shape and small size of the youngest whorl shows that they don’t possess a cyrtoneritimorph protoconch.

The fact that two quite different protoconch morphologies occur in Devonian platyceratids (compare Figs 3 and 4) suggests that they do not form a monophyletic group. This conclusion seems to be also supported by the very long stratigraphic range of the cyrtoneritimorph protoconchs which can be traced from the Early Ordovician to the Late Permian, an interval of 250 million years duration (Frýda 1998a–c, Bandel & Frýda 1999, Frýda & Rohr 2004). The existence of two, not closely related groups complicates analysis of the phylogenetic position of platyceratid gastropods within the class Gastropoda. In addition, this situation also resulted in a nomenclatorial problem – it is uncertain what family-level names should be used for these gastropods. The genus *Platyceras* Conrad, 1840, is based on *Platyceras vetusta* (Sowerby, 1829) from the Lower Carboniferous of Queens Country, Ireland. The

protoconch of this species is unknown and so there is no evidence for its placement either in the Cyrtoneritimorpha or in “platyceratids” having tightly coiled, orthostrophic protoconchs. If the type species of *Platyceras* has a tightly coiled, orthostrophic protoconch like the Silurian and Devonian “*Platyceras*” sp. illustrated here (Fig. 4A–C, E, F, H, I), then the model proposed by Bandel & Frýda (1999) may be accepted (see also Bouchet *et al.* 2005). The Platyceratidae will include platyceratid gastropods with tightly coiled, orthostrophic protoconchs similar to those found in the Paleozoic Naticopsidae (Yoo 1994, Nützel & Mapes 2001, Bandel 2002a, Nützel *et al.* 2007a). Moreover, the families Vltaviellidae Bandel & Frýda, 1999, and Orthonychiidae Bandel & Frýda, 1999, will unite “platyceratid” gastropods with cyrtoneritimorph protoconchs. But if the type species of *Platyceras* also has a cyrtoneritimorph protoconch like *Praenatica* or *Orthonychia*, then the families Vltaviellidae and Orthonychiidae may represent junior synonyms of the Platyceratidae. Note that a similar situation occurs in the genus *Orthonychia* (being often considered to represent a subgenus of *Platyceras*), which is based on the Devonian species *Orthonychia subrectum* (Hall, 1859), which also has an unknown protoconch morphology. Protoconchs of Paleozoic species of *Orthonychia* have cyrtoneritimorph morphology (e.g., Fig. 5C, D). However, Triassic *Orthonychia alata* (Laube 1869) has the typical protoconch of post-Paleozoic neritimorphs. For this reason the species was placed into a new genus *Pseudorthonychia* Bandel & Frýda, 1999.

Platyceratids as a stem group of neritimorphs

Knight *et al.* (1960) considered the Platyceratoidea to represent an independent superfamily of the Trochina and, thus, placed them into the Archaeogastropoda. However, not only Platyceratoidea, but all neritimorphs were traditionally placed in the archaeogastropods mainly because they share a rhipidoglossate radula with the vetigastropods (e.g., Troschel 1856, Thiele 1929–35, Wenz 1938–44, Knight *et al.* 1960). Bandel (1982) studied in detail the ontogeny and protoconch morphology of extant neritimorphs and he concluded that they represent a separate evolutionary lineage which is distinct from other archaeogastropods. This conclusion was later supported by anatomical and molecular data (e.g., Haszprunar 1988, Healey 1988, Sasaki 1998, Ponder & Lindberg 1997, Kano *et al.* 2002). Ponder & Lindberg (1997), similar to Haszprunar (1988), considered the Neritimorpha to represent an “early archaeogastropod offshoot”, thus, the neritimorphs according to their interpretation form a sister group of all gastropods except the Patellogastropoda. The latter model resulted in the conclusion that planktotrophy originated twice in the

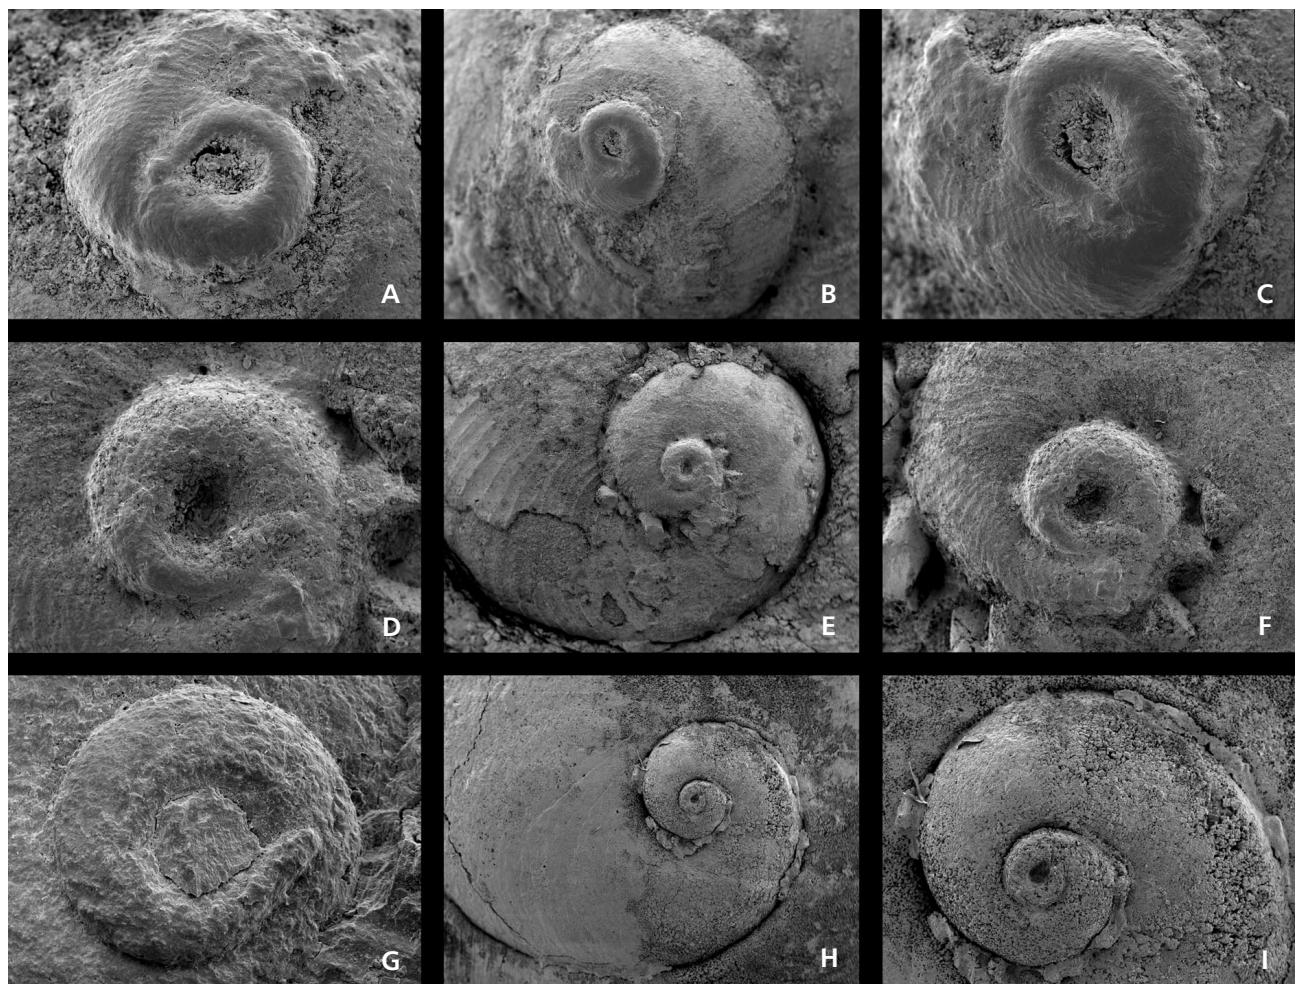

Figure 3. Cyrtoneritimorph protoconchs in species of *Praenatica* Barrande in Perner, 1903, and *Kramerella* Frýda & Heidelberger, 2003. • A–C – cyrtoneritimorph protoconch in *Praenatica cheloti* (Oehlert & Oehlert, 1887) from the Saint Roch quarry (N of Saint Ouen-des-Toits and about 3 km S of La Baconnière) figured here as Fig. 2A–D, A \times 42, B \times 18, C \times 50. • D–F – cyrtoneritimorph protoconch in *Praenatica cheloti* (Oehlert & Oehlert, 1887) from La Baconnière, topotype No. ML-PAL-00411, D \times 60, E \times 13, F \times 37. • G – cyrtoneritimorph protoconch in holotype of the Silurian *Kramerella hornyi* Frýda & Heidelberger, 2003, from the Kopanina Formation (Gorstian, early Ludlow, early Late Silurian) of the Barrandian area, G \times 95. • H, I – fragment of cyrtoneritimorph protoconch in Early Devonian *Praenatica gregaria* Barrande in Perner, 1903, from the Koněprusy Limestone (Praha Formation, Pragian–lower Emsian) of the Barrandian area, the Schary collection No. 193178, the Museum of Comparative Zoology, Harvard University, H \times 9, I \times 21.

evolution of the Gastropoda (Haszprunar 1995), in the Neritimorpha and in the Apogastropoda (uniting Caenogastropoda and Heterobranchia). New molecular studies, however, supported the earlier published position of the Vetricigastropoda as a sister group of the Neritimorpha, Caenogastropoda and Heterobranchia, as well as the monophyly of the Neritimorpha (Colgan *et al.* 2003, McArthur & Harasewych 2003, Kano *et al.* 2002, Aktipis *et al.* 2008).

The Paleozoic platyceratoidean gastropods were considered to belong to the Neritimorpha (Bandel 1992, Bandel & Frýda 1999, Frýda 1999). Besides their general shell shape, the presence of a thick calcitic outer shell layer (Batten 1984) often bearing coloured bands (Yochelson 1956, Kříž & Lukeš 1974, Yochelson & Kříž 1974, Blodgett & Johnson 1992) seems to be conformable

with this view. However this opinion could not be tested by the shape of their protoconchs. The oldest evidence for neritimorph protoconchs of the same type as is found in living marine neritimorphs (see Bandel 1982) was documented in the Upper Triassic (Bandel & Frýda 1999, Bandel 2007, and references therein). Bandel (2007) showed that several groups of the neritimorphs can be traced from the Triassic to Recent and that species diversity of neritimorphs was much higher in the Triassic reef environment than in any modern reefs. He documented 36 neritimorph species from tropical reefs of the Late Triassic St Cassian Formation in the Tethys Ocean. Only the living species of *Neritopsis* can be regarded as relatively closely related to some of these species from the Cassian Reef. Bandel (2007) noted that other Triassic species can

be placed into the superfamilies Neritopoidea and Neritioidea, but not in any of the modern families. On the other hand, according to this author some Triassic neritimorphs (subfamilies Ampezzonaticopsinae Bandel, 2007 and Hologyrinae Bandel, 2007) belong to the family Naticopsidae. The latter family was highly diverse from Devonian to Permian time. The genus *Naticopsis* M'Coy, 1844 is based on *Naticopsis phillipsii* M'Coy, 1844 from the Lower Carboniferous of Ireland and as is typical for Paleozoic gastropods in that its protoconch as well as its shell structure are unknown. Bandel (2007) noted that the naticopsid lineage is extinct, thus, it has no connection to modern Neritimorpha, similar to the vast majority of Late Triassic neritimorphs.

There is no evidence in the Paleozoic for the presence of the characteristic, strongly convolute neritimorph protoconchs (representing an apomorphy of the neritimorph crown group). On the other hand, there is rich evidence for the high diversity and morphological disparity of the neritimorphs having this protoconch type in the Late Triassic (Bandel 2007). These facts suggest that the strongly convolute larval shell of the neritimorphs (protoconch II) originated after the Permian/Triassic mass extinction event and before the Late Triassic. An analysis of the neritimorph phylogeny published by Kaim & Sztajner (2005) and mainly based on operculum morphology resulted in similar conclusions (see also Kano 2006, Bandel 2008). According to the latter authors, modern Neritimorpha split into Neritidae (internally resorbed) and Neritopsidae (not resorbed) at the Paleozoic/Mesozoic transition. Molecular studies also provide evidence for the basal position of the Neritopsidae, thus, it represents a sister group of all living Neritimorpha (Kano *et al.* 2002). This model fits well with the post-Paleozoic fossil record.

However which Paleozoic group is ancestral to the Neritimorpha? Knight (1933) and Knight *et al.* (1960) suggested that the Paleozoic naticopsids form the stem group of modern Neritimorpha. This opinion was based only on similarities in teleoconch morphologies of post-Paleozoic Neritimorpha and Paleozoic Naticopsidae. Investigation of protoconch morphologies has revealed new data for both of the latter two groups. Naticopsid protoconchs are simple, smooth and orthostrophic (Yoo 1994, Nützel & Mapes 2001, Bandel 2007, Nützel *et al.* 2007a), thus, they are similar to those found in some Silurian and Devonian "platyceratid" (see Fig. 4). It is noteworthy that there is no principal difference between this protoconch morphology and the protoconchs known in the Caenogastropoda (Nützel *et al.* 2007a, Frýda *et al.* 2008a). The oldest members of the Caenogastropoda (based on protoconch morphology) are documented from the Lower Devonian strata (Frýda 2001, Frýda & Blodgett 2004, Cook *et al.* 2008) and they later formed a dominant group in the Late Paleozoic gastropod faunas (Knight 1933, Nützel 1998, Bandel

2002a, and references therein). Close similarities in the protoconch morphology of naticopsids and some "platyceratids" on one hand and caenogastropods on the other hand could indicate that the Neritimorpha and Caenogastropoda are closely related and that the convolute larval shell of the modern Neritimorpha is a relatively new feature (Nützel *et al.* 2007a, Frýda *et al.* 2008a).

Data on protoconch morphologies (orthostrophic protoconchs consisting of embryonic and larval shells) suggest that the Paleozoic Naticopsidae as well as some "platyceratids" may represent a stem group of modern Neritimorpha, as was already noted by Knight (1934). The occurrence of Late Triassic naticopsids having the same teleoconch features as undoubtedly Triassic neritimorphs (*i.e.*, those having characteristic protoconchs only known in the neritimorph crown group among all living gastropods) also supports this model (Bandel 2007). If this is correct, then the Neritimorpha are a sister group of caenogastropods or all apogastropods and they had to have split from the caenogastropods before the Devonian (the oldest evidence for caenogastropods based on protoconch data). The typical neritimorph protoconch is an apomorphy only for the neritimorph crown group and it probably originated after the Permian/Triassic mass extinction event, but before the Late Triassic.

Platyceratids as a stem group of patellogastropods

A quite different opinion on the higher phylogenetic position of platyceratids was published by Ponder & Lindberg (1997) based on data regarding their shell biomineralization which was published earlier by Carter & Hall (1990). The latter authors found a regularly foliated shell microstructure in the Platyceratoidea. Except for the platyceratoids, this microstructure only occurs in living and fossil patellogastropods. Patellogastropoda are generally considered to represent a sister group to all other living gastropods (Glikov & Starobogatov 1975, Lindberg 1988, Ponder & Lindberg 1997, Aktipis *et al.* 2008). Living patellogastropods with limpet-shaped shells are exclusively marine and mostly occur on rocky shores in all continents. The oldest undoubtedly evidence for the Patellogastropoda is from Late Triassic strata (Hedegaard *et al.* 1997). The fact that there is no sure evidence for Paleozoic members of the Patellogastropoda is surprising because if they are really the first gastropod offshoot (Ponder & Lindberg 1997), they had to have split off from the rest of the gastropods (*i.e.* orthogastropods) before the Early Ordovician (Frýda & Rohr 2004, Frýda *et al.* 2008a). Thus, there is no certain fossil record for the first half of their presumed evolution as an independent gastropod clade (*i.e.*, missing data for about 250 Ma). This controversy has been explai-

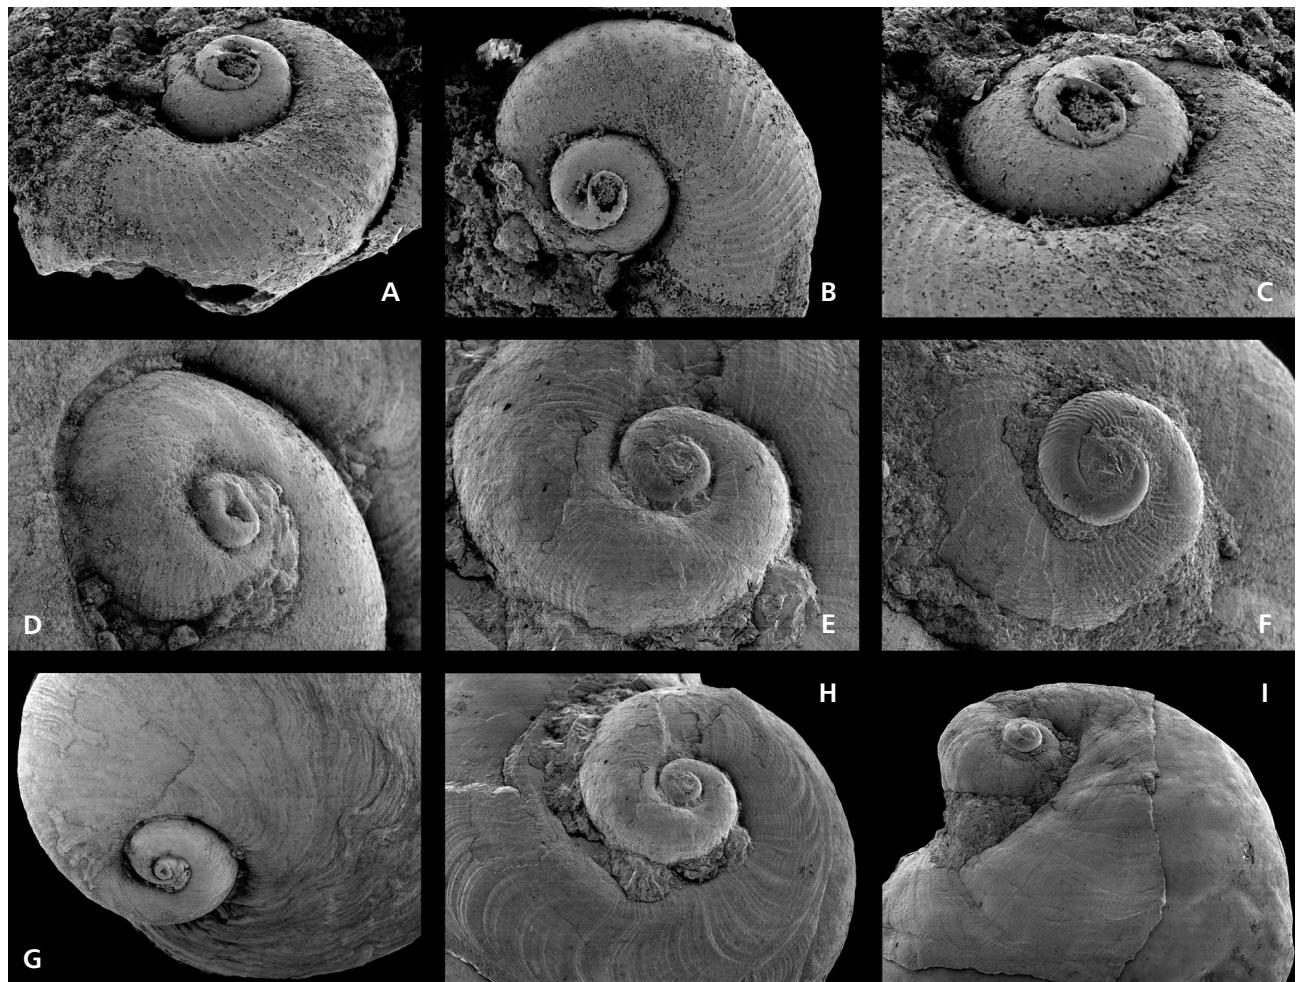

Figure 4. Protoconchs in the Silurian and Devonian platyceratids from the Barrandian area and Brittany. • A–C – orthostrophic, tightly coiled protoconch in *Platyceras* sp. from the Chýnice Limestone (middle Emsian) from the Čeřinka locality near Bubovice (SW of Prague), specimen CGS JF 894, A \times 60, B \times 58, C \times 105. • D, G – cyrtoneritimorph protoconch in *Praenatica cheloti* (Oehlert & Oehlert, 1887) from La Baconnière, type specimen No. ML-PAL-00412, D \times 27, G \times 6. • E, H – orthostrophic, tightly coiled juvenile whorl in the Late Silurian *Platyceras* sp. found close to the village of Lochkov (SW of Prague), specimen CGS JF 892, E \times 27, H \times 12. • F, I – orthostrophic, tightly coiled protoconch in another specimen of the Late Silurian *Platyceras* sp. found close to village of Lochkov (SW of Prague), specimen CGS JF 893, F \times 30, I \times 6.

ned by either their adaptation to intertidal environments that provide a relatively poor fossil record or by the opinion that the Paleozoic patellogastropods had coiled shells not hitherto recognized among Paleozoic gastropods. The nature of early patellogastropod shells is still a matter of debate. Haszprunar (1988) hypothesized that the limpet shell is a plesiomorphy retained by patellogastropods. However, Ponder & Lindberg (1997; also Lindberg & Ponder 2001) argued that this was a parallelism and that the last common ancestor of extant gastropods was coiled. Such an opinion had already been published by Knight (1952) who suggested that the patellogastropods were derived from the pleurotomarioids. This model seems to fit with the protoconch nature of both groups (absence of true larval shell). If this model will be accepted then the very complex microstructure of the patellogastropod shells (MacClintock 1968,

Bandel & Geldmacher 1996, Sasaki 1998, Fuchigami & Sasaki 2005) had to be secondarily evolved, maybe because of their adaptation to intertidal environments.

The phylogenetic model which considers platyceratoideans to represent possible coiled ancestors for the patellogastropods is only supported by the above-mentioned sharing of regularly foliated shell microstructure. However, there are some doubts if this microstructure is really identical in both groups (see Bandel & Geldmacher 1996). In addition, we see a more serious fact which testifies against this phylogenetic model – the nature of early shell ontogeny in both groups. The patellogastropods share the same pattern of early shell ontogeny with archaeogastropods such as the Vetigastropoda (Bandel 1982, Sasaki 1998), developing their protoconchs without a true larval shell (protoconch II). This strategy was documented

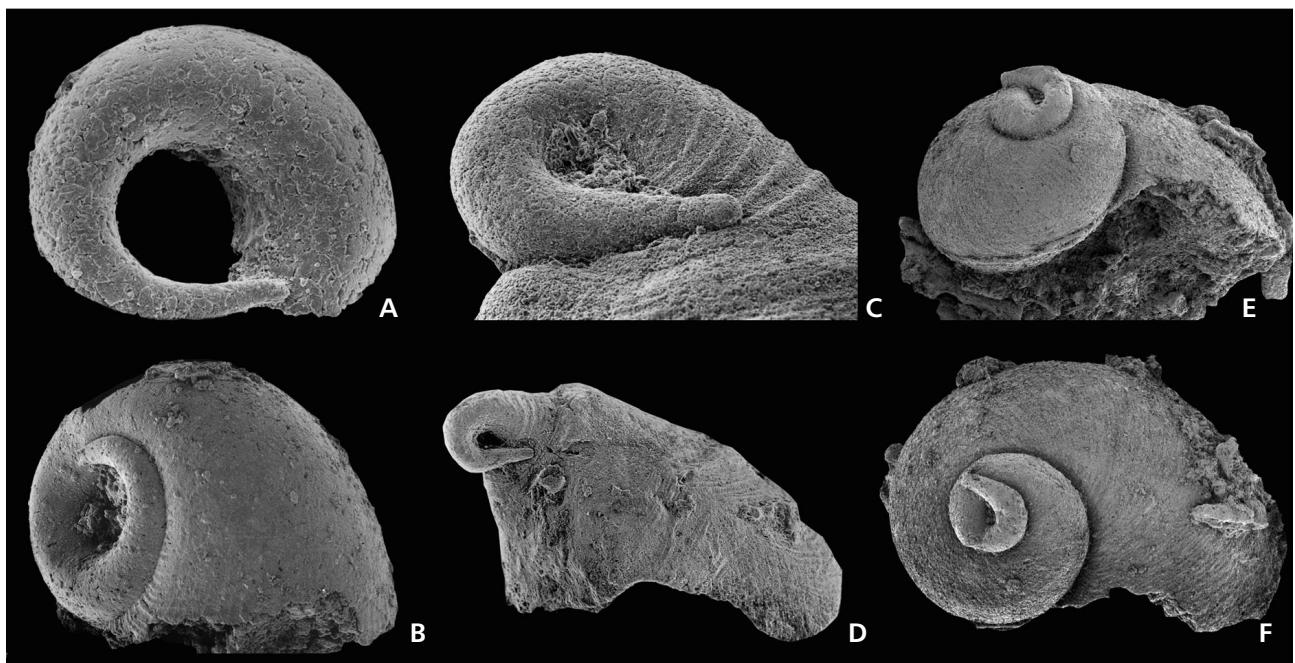

Figure 5. Protoconchs in the Devonian and Carboniferous cyrtoneritimorph gastropods. • A–D – cyrtoneritimorph larval shell (A) and early teleoconch (B) in the Early Devonian (Lochkovian) *Vltaviella reticulata* Frýda & Manda, 1997, SW Prague, A $\times 55$, B $\times 32$. • C, D – cyrtoneritimorph protoconch larval shell (C) and teleoconch (D) in the Carboniferous *Orthonychia parva* (Shumard & Swallow, 1858) from the St. Louis outlier of the Des Moines group in the Pennsylvanian of Missouri, C $\times 60$, D $\times 20$. • E, F – teleoconch in Middle Devonian *Eifelcyrtus blodgettii* Frýda & Heidelberger, 2003, from the Scheid Member of the Cuerten limestone (early Givetian, late Middle Devonian; Soetenicher Mulde), E $\times 30$, F $\times 32$.

to be stable for at least the last 400 Ma in the case of archaeogastropods (Frýda 1999, Frýda *et al.* 2008a). On the other hand, both groups of platyceratids (cyrtoneritimorph “platyceratids” as well as “platyceratids” having tightly coiled protoconchs) as well as the naticopsids, developed true larval shells (protoconch II). Thus, if the platyceratoids are a stem group of the patello-gastropods, then the patello-gastropods had to lose the ability to develop true larval shells (protoconch II) during the Late Paleozoic or Early Triassic. Taken together, the interpretation of platyceratoid gastropods as the stem group of patello-gastropods based on sharing of the same shell microstructure is in conflict with the pattern of their early shell ontogeny.

Two years ago Sutton *et al.* (2006) reported the discovery of an unusually well preserved gastropod with fossilized soft tissues from the Lower Silurian (Wenlock Series) Herefordshire Lagerstätte of England. This gastropod was assigned to the Platyceratidae on the basis of its simple subcircular aperture, trochiform shell and the absence of ornamentation. Its study has revealed detailed data on the digestive system as well as morphological data on the gonads, digestive gland, pedal muscle, radula, mouth and foot. According to Sutton *et al.* (2006) the digestive system is the most informative phylogenetically of all the preserved soft-tissue characters. These anatomical data together with the absence of the operculum were interpreted as suggesting that platyceratids were symbiotic

rather than predatory on their hosts. However, a more important conclusion made by Sutton *et al.* (2006) is that anatomical characters of their *Platyceras?* sp. suggest its patello-gastropod affinity rather than neritopsine [= neritimorph] affinity. However, this undoubtedly important discovery includes one serious problem. Unfortunately teleoconch features (simple subcircular aperture, trochiform shell and absence of shell ornamentation) used for assignment of the gastropod from the Herefordshire Lagerstätte to the platyceratids are not sufficient for such a taxonomical conclusion. Similar teleoconch shapes may be found in several unrelated Paleozoic gastropods because the severe architectural restrictions caused a common occurrence of morphological convergence in their teleoconchs (see Wenz 1938–1944, Knight *et al.* 1960). In contrast to the teleoconch features, the protoconch morphology might be diagnostic of large gastropod clades. By courtesy of M.D. Sutton (pers. comm., 2008) we had the chance to examine in detail the apical view of a shell from the Herefordshire Lagerstätte (Sutton *et al.* 2006, fig. 1f). Unfortunately no traces of protoconch morphology were observed. The discovery made by Sutton *et al.* (2006) is important for the interpretation of the patello-gastropod phylogeny (the Silurian gastropod from the Herefordshire Lagerstätte may represent a coiled ancestor of the Patello-gastropoda), but cannot be used as evidence for platyceratid and patello-gastropod affinity.

Conclusions

New discoveries of protoconch morphologies contribute to our knowledge of platyceratid phylogeny. Several key points relating to this problem are summarized below:

1. Species of the Early Devonian platyceratid *Praenatica* Barrande in Perner, 1903 developed a typical cyrtoneritimorph protoconch. The same protoconch type was earlier documented in *Orthonychia* Hall, 1843. Both of these taxa have often been considered to be subgenera of *Platyceras* Conrad, 1840.
2. Quite different protoconch morphology (orthostrophic and tightly coiled) was recently documented in some Silurian and Devonian species placed in the genus *Platyceras*. The same type of the protoconch was earlier found in different species of the Naticopsidae.
3. The present data thus suggests that Paleozoic platyceratids represent a diphyletic group. However, development of true larval shells in both "platyceratid" groups argues against the hypothesis that Paleozoic platyceratids represent a stem group for the Patellogastropoda.
4. Paleozoic evolution of the neritimorph clade is uncertain, but their derivation from the Paleozoic "platyceratids" with tightly coiled protoconchs or from the naticopsids seems to be probable. A strongly convolute neritimorph protoconch (apomorphy of the neritimorph crown-group) probably originated after the Permian/Triassic mass extinction event and but before the Late Triassic.

Acknowledgements

This work was supported by grants from the Grant Agency of the Czech Republic (205/08/0062), the Czech-American Cooperation Program (Kontakt ME08011), and a CGS grant (3325). The revision of Lower Devonian gastropods from the Massif Armorican was made possible through an invited professorial position for J. Frýda at the Université de Bretagne Occidentale (Brest) in April 2008. The authors thank Doris Heidelberger (Oberursel), Robert B. Blodgett (Anchorage), and Wojciech Krawczyński (Sosnowiec) for their helpful reviews. The authors also thank Jessica Cundiff (Curator of the Schary collection, Museum of Comparative Zoology, Harvard) and Jérôme Treguier (Curator of the Oehlert's collection, Musée d'Histoire Naturelle, Laval) for providing the material used in this study.
